Nathan Mentzer is an Associate Professor in the Engineering/Technology Teacher Education Program at Purdue University, jointly appointed in Technology Leadership and Innovation and Curriculum and Instruction. Hired as a part of the strategic P12 STEM initiative, he prepares Engineering/Technology candidates for teacher licensure. Dr. Mentzer’s efforts in pedagogical content knowledge are guided by a research theme centered in student learning of engineering design thinking on the secondary level. Nathan was a former middle and high school technology educator in Montana prior to pursuing a doctoral degree. He was a National Center for Engineering and Technology Education (NCETE) Fellow at Utah State University while pursuing a Ph.D. in Curriculum and Instruction. He can be reached at nmentzer@purdue.edu.

Dawn Laux is a Clinical Assistant Professor in the Department of Computer and Information Technology (CIT) at Purdue University. She received her PhD in Human Computer Interaction from Iowa State University in 2014. As a faculty member since 2009, Dr. Dawn Laux has made significant contributions to learning and engagement. Dr. Laux has focused her scholarship around a theme of student persistence based on her experience in developing core curriculum, engaged in increasing diversity in the computing field, and research on the impacts of collaborative learning. She can be reached at dlaux@purdue.edu.

Angelika Zissimopoulos is Associate Director for STEM education at the University of Chicago's Chicago Center for Teaching. Leveraging both her pedagogical training and doctoral training as a biomedical engineer, she consults with faculty and graduate students on pedagogy and course design, particularly in STEM fields. She also collaborates with faculty and staff to conduct educational research in a broad range of disciplines. Prior to coming to Chicago, Dr. Zissimopoulos was an instructional developer at Purdue University, where she was also part of the human-centered design course teaching team. She can be reached at zissimopoulos@uchicago.edu.

K. Andrew R. Richards is an Assistant Professor of physical education in the Department of Kinesiology at the University of Alabama. Richards’ research focuses on the training and socialization of physical education teachers, with a focus on role stress, burnout, and resilience. He completed a Bachelors degree in physical education at Springfield College (MA), and Master’s and doctoral degrees in physical education pedagogy at Purdue University prior to working as a post-doctoral research associate with the Center for Instructional Excellence at Purdue. In the Center, Richards assisted with the evaluation of a large-scale course transformation project called IMPACT (Instruction Matters: Purdue Academic Course Transformation). He can be reached at karichards2@ua.edu.
Abstract

Peer evaluation of team member effectiveness is often used to complement cooperative learning in the classroom, by holding students accountable for their team contributions. Drawing on the tenants of self-determination theory, this study investigated the impacts of formative peer evaluation in university level team-based design projects. The hypothesis was that the introduction of formative peer evaluation cycles would result in a more student-centered learning climate, increased competence, reduced doubt, and improved student learning. Two semesters were compared in this quasi-experimental study where results of peer evaluation became modifiers to students’ grades in the final project. In only one of the semesters, peer evaluation was also used multiple times formatively to provide students with feedback and encourage changes in behavior without impacting grades. When formative peer evaluation was implemented, students earned higher grades on the final project and in the course and perceived a more student-centered learning environment, more competence, and less doubt about the course.

Keywords: Peer evaluation, Team Member Effectiveness, Learning Climate, Self-determination Theory
Peer Evaluation of Team Member Effectiveness as a Formative Educational Intervention

To be a successful member of the modern workforce, an effective employee must anticipate change and adapt quickly, be able to apply critical thinking skills, collaborate professionally with others, and self-monitor performance in teams (National Research Council, 2011). Active learning techniques that encourage student engagement in the learning process, such as cooperative learning, provide opportunities for students to develop critical thinking skills, engage in collaboration, and evaluate team effectiveness. This study investigated the impacts of evaluating and communicating team member effectiveness as an ongoing, iterative feedback mechanism (formative evaluation) on university freshman student performance and perceptions in a technological design course at a major US research institution.

Prior research has found that student achievement is improved with the use of cooperative learning as opposed to an individual approach to learning (approximate effect size of approximately 0.50, which is significant statistically and practically) (Prince, 2004; Smith, Sheppard, Johnson, & Johnson, 2005). Research studies have reported that a group achieves greater benefits from the knowledge gained by each individual member (Johnson, Johnson, & Smith, 1998; Prince, 2004; Smith et al., 2005). Johnson, et al. (1998) also noted that cooperative learning (as opposed to working alone) improves the quality of student relationships (effect size =0.55). Johnson and colleagues reported this finding is consistent across ethnic, cultural, language, social class, ability, and gender groups by measuring internal attraction, esprit de corps, cohesiveness, and trust. Finally, evidence indicates that the psychological adjustment to college life positively correlates with cooperative learning (Smith et al., 2005). Self-esteem has
also been found to increase with the use of cooperative learning (Prince, 2004). Millis (2010) suggested that group work can encourage critical thinking while inspiring students to value the contributions of others.

Free-Rider Problems in Collaborative Learning

Challenges have been noted regarding cooperative learning. Notably, one concern for students is how to adequately evaluate participation among team members (Topping, 2009). In research pertaining to attitudes toward social loafing (Jassawalla, Sashittal, & Malshe, 2009), students perceived that non-participating team members submit poor quality work and negatively contribute with distractive and disruptive behaviors. Jassawalla, Sashittal and Malshe’s data showed that student apathy and disconnectedness were precursors to the behavior, therefore causing more work for the other team members.

One way to address the free-rider problem is with the use of peer evaluation. Brooks and Ammons (2003) found that by implementing a peer evaluation system at the conclusion of a series of short term group projects, free-rider problems can be reduced by shaping student attitudes about their own participation. Peer evaluation of team member effectiveness is defined in this study as having each teammate rate themselves and their teammates on multiple dimensions of team member effectiveness. Peer evaluation of team member effectiveness has been found to be an effective accountability tool in various disciplines such as Nursing, Business, and Engineering (Brooks & Ammons, 2003; Brutus & Donia, 2010; Elliott & Higgins, 2005; Fellenz, 2006; Kao, 2013; Kench, Field, Agudera, & Gill, 2009; Maiden & Perry, 2011; Tessier, 2012). Peer evaluations complement cooperative learning when it comes to individual accountability, social skills, and group processing, while improving the overall effectiveness of
group performance (Brutus & Donia, 2010). In a study by Elliott & Higgins (2005), the majority of students considered self and peer evaluations to be a fair system for measuring the contribution made by each member of the group. The participants also reported that a majority of students found that the peer evaluation process motivated them to actively participate in the assessed group work.

Timeliness of Peer Evaluations

In a comparison-of-methods study, Baker (2008) discussed peer evaluation methodology and described the difference between formative and summative peer evaluation. When using peer evaluations for formative purposes, evaluation occurs during the project and results are provided to students prior to the project ending so that students are given the opportunity to improve team skills before the conclusion of the group activity (Cestone, Levine, & Lane, 2008). Summative peer evaluation is typically administered at the end of a team project and members of the team evaluate the individual performance based on a predetermined set of requirements (Elliott & Higgins, 2005; Goldfinch & Raeside, 1990; Holland & Feigenbaum, 1998). Since summative peer evaluation takes place at the end of the project, individuals do not have the opportunity to take corrective action as they might with formative evaluation (Baker, 2008; Brooks & Ammons, 2003; Reese-Durham, 2005). In a study on the perceptions of social loafing, Jassawalla, Sashittal, & Malshe (2009) discovered that some of the students who received a summative peer evaluation were unaware, until the end of the team activity, that their participation was perceived as lacking. These self-reports may be biased as students claim to be unaware that they were not meeting teammate’s expectations when in fact this is a defense mechanism (Barbara, 2002). However, assuming some students were unaware, Jassawalla et al. (2009) suggested that instruction on teamwork skills could alleviate this issue. Based on the developmental peer evaluation research,
this level of disconnectedness within the team could possibly be alleviated with peer feedback
during the activity rather than after the activity is over. A formative evaluation earlier in the team
project may be the needed motivation to participate (Baker, 2008).

Understanding Human Motivation

Self-Determination Theory (Deci & Ryan, 1985; Deci & Ryan, 2000) provides a framework to
explain how human motivation influences behavior. Central to Self-Determination Theory is the
notion that humans have three basic psychological needs that they seek to satisfy through their
interactions with one another and the environment: relatedness, autonomy, and competence (Deci
& Ryan, 1985). Relatedness refers to individuals’ feelings of connectedness to others and leads
to a sense of belonging within the social setting. Autonomy results from having the ability to
make choices and exercise a sense of volition, but does not mean that individuals act
autonomously and without supervision. Rather, autonomy can be fostered when students have the
ability to make choices within a structure that is defined by the instructor. Competence is related
to the notion of self-efficacy (Bandura, 1986) and relates to individuals’ feeling that they are able
to meet contextual demands. The inverse of competence is sometimes referred to as doubt and
highlights situations in which individuals do not feel able to accomplish tasks or achieve goals.

Self-Determination Theory has been applied to educational settings to explain student motivation
that results from different types of learning environments (see Black & Deci, 2000; Levesque-
Bristol, Knapp, & Fisher, 2010). When these interactions foster student-centered learning
environments, students’ basic psychological needs will be satisfied and they will be more
intrinsically motivated to learn. In contrast, when learning environments are perceived to be
controlling and instructor-centered, the basic psychological needs are less likely to be satisfied
and motivation is extrinsically regulated (Deci, Ryan, & Williams, 1996). When students are extrinsically motivated they feel as if they are engaging in learning activities in order to achieve a reward (e.g., a good grade) or avoid a punishment (e.g., a failing grade) and are less likely to feel personally invested in the coursework. Related to Self-Determination Theory, active learning strategies such as cooperative learning can help to create student-centered learning environments, which satisfy the basic psychological needs and lead to more positive perceptions of the learning environment and better student-level outcomes.

Purpose of this study

The purpose of this study was to investigate the impact of using peer evaluation as a formative learning tool. It was hypothesized that peer evaluation might also have potential to improve student performance if used as a formative tool during early stages of the final project in addition to use as a summative tool at the conclusion. The underlying assumption here was that not all teams are fully functional. The hypothesis driving this inquiry was that peer evaluation used as formative feedback on a long term final project will improve student performance, improve students’ perceptions of the learning climate, increase perceived competence, and reduce perceived doubt over a comparison group using cooperative learning with only summative feedback. This hypothesis builds on the work of Brooks and Ammons (2003) who suggested that multiple peer feedback evaluation points reduce the occurrence of free-riding when used after each separate learning module. While Brooks and Ammons (2003) administered multiple peer evaluation points, each was summative and the main focus of their study was on alleviating free-riding on subsequent learning modules rather than the effects of formative peer evaluation on student performance during an extended project.
Research Questions

Two research questions guided the investigation. Multiple data sets and analysis strategies were required to address each question and will be discussed separately. The research questions were:

1: Does formative peer evaluation improve student learning, as measured by final project grade and course grade, over summative only peer feedback?

2: Does formative peer evaluation improve students’ perceptions of the learning climate, increase competence, and reduce doubt over summative only peer feedback?

Methods

Data for this quasi-experimental study were drawn from students enrolled in a university freshman level design thinking course in the fall of 2012 and fall of 2013. In both semesters, peer evaluation was used as a summative tool to impact student grades based on the degree to which their teammates perceived that they contributed to the final project. The use of formative peer evaluation was piloted during the spring of 2013, and implemented in the fall of 2013. Therefore, data from the fall of 2013 included both formative and summative peer evaluation ratings while data from the fall of 2012 only included summative peer evaluation. The Institutional Review Board approved this study as exempt, as it involved typical educational procedures. All data were made anonymous and analyses were not conducted until after the conclusion of the fall of 2013.

Learning Environment

The course chosen for the study was a college core course focused on design thinking in a major research university. Most students were freshmen or transfers (mainly from other colleges at the University). This user-centered design course was initially implemented in the 2011-12 academic
year as the first course in a three course sequence required for all undergraduate students in the college. Faculty implementing the course participated in course redesign workshops the year before this study was implemented. Faculty members worked with pedagogical, technological, and information literacy experts to redesign the course from a traditional, large lecture format to a flipped model, where a blend of distance and face-to-face modalities were implemented. Changes were made in learning outcomes, pedagogy, and content using research-backed strategies for sound student-centered teaching and learning. Changes made and described here as part of a course redesign were completed prior to implementation of this study.

During the semesters related to this research study, students spent substantial time engaged in small group learning experiences and team based projects. Sections of the course were limited to 40 students each and situated in a technology-enabled classroom where each student had a computer. Students were arranged in pods ranging from 4-6 students, and each pod was capable of projecting on a large screen with a data projector. White boards and cameras were accessible for group work and documentation.

Multiple instructors were used in course implementation. However, to control for instructor differences, data for this study were drawn from classes taught by one tenure-track assistant professor who was in his fourth and fifth years at the university. Course content and delivery were held constant during the study, with the only change being the treatment which was the addition of formative feedback during the fall of 2013.

Learning outcomes for the course were developed and approved to include the following: Students will be able to:

1. Write a narrowly focused problem statement.
2. Apply ethnographic methods to understand technological problems.
3. Develop a search strategy, access technical data-bases and evaluate results and source quality.
4. Create a technical report documenting results of the design process.
5. Manage design projects, develop project timelines, and negotiate individual responsibilities and accountability in the team environment.
6. Apply strategies of ideation to develop novel and innovative solutions.
7. Rapidly prototype solutions for purposes of design, testing, and communication.

Learning experiences based on these outcomes were developed and thematically linked to the domain of technology through the lens of design. Students began the semester generally working individually outside of class and in pairs or small groups in class. As the semester progressed, students gradually transitioned to working outside of class in small groups and working in small and large group format in class. Students typically completed two assignments per week. One assignment was given prior to each class session to engage students in content and prepare them for class, and one assignment was provided in class.

Assignments were based on course materials and included readings, videos, field work, and student creation of artifacts. As an example, students would read about design thinking, watch a video on ethnography in the context of a design problem, conduct and document observations, and synthesize results based on their data collection leading to defining a problem. An example assignment would include developing constraints and criteria, refining them to be measurable, and identifying solutions for potential development. Students have online access to procedures and rubrics used to grade their submissions. Submissions were graded quickly (less than one week) and returned to the students with feedback and explanation of missed points so that students may improve their approach to coursework.
The course grade included 1000 points and each assignment was weighted based on its relative complexity so the student could easily interpret a percentage of their semester grade associated with the assignment. Small projects introduced students to design thinking using a human-centered design model including problem definition, stakeholder identification, benchmarking, solution generation, decision making, prototyping, feedback from stakeholders, and presentation. Students engaged in the final project during the second half of the semester. The project provided students with a context to apply concepts learned during the first half of the course to an eight week learning experience during the second half of the course, culminating with a presentation of the refined conceptual design. Prototypes at the conclusion of the course demonstrated a proof of concept, but were not ready for implementation. Final project topics had loose boundaries where students from various disciplines in the college had autonomy to focus on a common area of interest which may or may not have been directly central to their major (though the connection was encouraged). In both fall of 2012 and fall of 2013, final projects were done in teams ranging from 2-6 students with the typical group being 4-5 students, which is consistent with research on cooperative learning (Slavin, 1991). Final project teams were created at the beginning of the project (around mid-term of the semester). Students self-selected and each team negotiated the definition of their team’s problem statement.

Treatment Method

Various methods of approaching peer evaluation have been developed and published including paper- and computer-based surveys. A web-based survey called the Comprehensive Assessment for Team-Member Effectiveness (CATME) was used in this study (available free for any educational institution, refer to www.CATME.org). CATME was selected because it has been determined to be reliable and valid (Loughry, Ohland, & Moore, 2007; Ohland et al., 2012),
which is essential when the results will be factored into student grades (Baker, 2008). The CATME instrument is a behaviorally anchored rating scale that describes behaviors typical of various levels of performance. Raters select the category of behaviors that most closely matches the actual behavior of each student (including themselves) on their team (Ohland et al., 2012). Five scales of teamwork were for this study and included: Contributing to the Team’s Work, Interacting with Teammates, Keeping the Team on Track, Expecting Quality, and Having Relevant Knowledge Skills and Abilities. The CATME interface asks students to rate themselves and their peers by selecting one of five behavioral descriptions per metric selected by the instructor. To consider Interacting with Teammates, for example (abbreviated for publication – more detail in the actual survey), does your peer: “ask for or show an interest in teammates’ ideas and contributions”, do they simply “respect and respond to feedback from teammates”, or do they “interrupt, ignore, boss or make fun of teammates?” (Ohland et al., 2005). The instrument quantifies these behavioral ratings such that high quality interactions receive a 5, average interactions receive a 3, and poor interactions receive a 1. After students were surveyed, the instructor released results back to the students. Results included the student’s self-rating compared to how their peers rated them and the average of their team for each metric.

In both comparison and treatment semesters, peer evaluations were administered during each of three major project deliverables as shown in Figure 1. During comparison semester, the peer evaluations were functionally summative because of the timing. The process of administering the survey and receiving feedback spanned at least two or more weeks and overlapped the next project component. Therefore, students did not have a chance to learn from the evaluation results prior to the next evaluation period. In the treatment semester, the evaluation process was rescheduled such that cycles of work, peer evaluation and feedback occurred more rapidly. This
rapid succession resulted in students having the ability to receive feedback prior to engaging in the next main deliverable and the evaluation experience was more formative in nature. During the treatment semester, peer evaluation was also implemented an additional two times during early stages of the final project. These two additional formative evaluations were spaced apart so that students had an opportunity to review results and discuss in class prior to the next iteration. As a result, the comparison semester experienced predominately summative evaluation while the treatment semester experienced five cycles of formative evaluation.

*Figure 1. Peer Evaluation Schedule for Comparison and Treatment Groups by Weeks in the Term and Design Project. The schedule is approximate and represents the survey administration to release time cycles. The survey is based on work that was done in the prior.*

In addition to the formative evaluations, the treatment group received an opportunity to experience peer evaluation at the end of a small short term group project early in the semester. This evaluation was not included in the data for the study as it was considered practice and not situated in the same team as the final project. During this practice evaluation, students were
required to complete a peer evaluation in a short term team project. Students were provided with instruction on how to give and receive feedback and interpret the results through a brief in a class discussion as suggested by Ceston et al. (2008). The second and third implementations of peer evaluation occurred at the beginning of the final projects after teams had formed. These evaluations had no impact on student grades and implementation timing provided students with an opportunity to practice with the interface, see the results, and discuss the results with their teammates and instructor.

Participants

There were 193 students enrolled in the course in the fall of 2012 and 140 enrolled in the fall of 2013. However, incomplete data were available for 13 students in the fall of 2012 (6.74%) and 19 students in the fall of 2013 (13.57%). Given that the incomplete data made it impossible to complete the analyses, these cases were omitted from the study. The final sample included 301 students (180 from fall of 2012, 121 from fall of 2013).

To answer research question one, data were drawn from all 301 students (259 males, 42 females) from a single instructor’s sections of the course for whom there were complete data. The average student was 20.63 years old ($SD = 3.52$). Most of the students were white ($N = 218; 72.4\%$) and born within the United States ($N = 283; 94\%$). Over three-quarters of the students were freshmen ($N = 241; 80.1\%$) with few representing sophomores ($N = 39; 13\%$), juniors ($N = 12; 4\%$), and seniors ($N = 9; 3\%$). The average student had a combined SAT math and verbal (SAT composite) score of $1119.97$ ($SD = 130.59$; approximately $69^{th}$ percentile$^1$), and an SAT writing score of $522.56$ ($SD = 73.26$; approximately $57^{th}$ percentile$^1$).

---

$^1$ Based on total group rankings for 2013 college bound high school seniors
Data to answer research question two were drawn from a subset of 80 students (64 males, 16 females) who completed a voluntary course perceptions survey at the end of each semester. There were 22 (12.22%) in the fall of 2012 while 58 (47.93%) were enrolled in the fall of 2013. The average student was 21.03 years old ($SD = 4.86$). Most of the students were white ($N = 65; 81.3$%), and most were born in the United States ($N = 75; 93.8$%). Three-quarters of the participants were freshmen ($N = 60; 75$%), while fewer represented sophomores ($N = 11; 13.8$%), juniors ($N = 3; 3.8$%), and seniors ($N = 6; 7.5$%). The average student had a SAT composite score of 1096.87 ($SD = 132.83$; approximately 66th percentile\(^1\)), and an SAT writing score of 513.13 ($SD = 74.35$; approximately 54th percentile\(^1\)).

Data Collection

**Demographic data.** Quasi-experimental research design assumes that both groups began the semester being similar and the instructor manipulated only the reported variable. Demographic data were gathered from the university database to permit comparisons between students in both semesters. Demographic data included SAT scores, class rank, gender, and racial/ethnic identity. Students were required to either take the SAT or the ACT college entrance exams. To standardize comparisons, ACT exam scores were converted to SAT comparable scores using the College Board Concordance Tables (The College Board, 2009).

**Student performance data.** Evidence of student learning data were collected in two forms: overall course grades and grades in components of the final project. Course grades were comprised of a series of assignments, typically two per week, where rubrics were used to evaluate authentic application experiences. Students had access to the rubrics in advance. Assignments included individual and small group work outside of class and in class.
The final project included three main components: a planning document, a written technical document, and a video. Each component was submitted separately with one or more weeks between submissions. The planning document included a Gantt chart, evidence of a finalized prototype, storyboard, and draft technical document. The video was limited to 60 seconds in length and was expected to communicate the problem, the existing but inadequate solutions, the proposed solution, and to demonstrate the proposed solution in action. Each of these three main final project components were rated with a rubric by the instructor and a teaching assistant. Prior to analysis, it was discovered that an error in the fall 2012 video rubric caused artificial final project grade inflation on this component (impact of this error on the semester grade may account for less than 1% of the overall course grade based on point values for some students in the fall of 2012 only). As a result, the video component of the final project was not considered in the analysis. In the final project, individual scores for each student were derived as a function of the group score and the individual student’s effectiveness as a team member. The group score was determined by rubrics used to measure quality of the submitted product. The individual score was the result of the group score multiplied by an individual effectiveness indicator extracted from CATME. The team effectiveness value ranged from approximately 0.20-1.05. This process was conducted to calculate individual student grades for the two components of the final project included in this study (Final Project Planning Component and Final Project Technical Document Component).

Overall course grade was determined by a series of existing assignments. Assignments, instructions, and rubrics were generated prior to the fall of 2012 collaboratively by a group of four faculty under the guidance of two course design experts from the University’s center for teaching and learning. The use of instructor-generated assignments as a measure of student
learning is consistent with previous studies (Fraenkel & Wallen, 2009; Gay, Mills, & Airasian, 2009). During both semesters of this study, the instructor and a graduate student grader met weekly to establish consistently and ensure calibration in the use of rubrics to grade the student submissions. Calibration was established between the graduate student and the instructor by discussing the assignment instructions and rubrics and collaboratively evaluating approximately 5% of the submissions. In addition, the instructor occasionally spot checked assignments after the graduate student had evaluated them to confirm appropriate application of the rubrics. In addition, students in the course had access to the rubrics before and after grading and were encouraged to review the rubrics to learn from their mistakes and also to confirm grading was done appropriately.

**Student perception data.** An online survey was administered at the end of each semester to measure students’ perceptions of the learning environment. This survey included measures of the Learning Climate, Competence, and Doubt (refer to Appendix A for instrument). The survey was administered by the University’s center for teaching and learning during both semesters of this study. The fall of 2012 was the first semester this survey was used on campus and the instructors, campus wide, were not well informed. As a result, instructors typically did not encourage students to participate which explains the low response rate during the fall of 2012.

Students’ perceptions of the Learning Climate were measured using the Learning Climate Questionnaire (Williams & Deci, 1996). The instrument measures students’ perceptions of the autonomy-supportiveness of the learning environment. High scores reflect a more student-centered learning climate, whereas lower scores reflect a more instructor-centered environment. Participants responded to the seven questions on a seven-point, Likert-type scale ranging from strongly disagree (1) to strongly agree (7). Example items included “my instructor provided me
with choices and options on how to complete the work,” “my instructor understood my perspective,” and “my instructor encouraged me to ask questions.” Validity and internal consistency for the instrument have been established through prior research (Levesque-Bristol et al., 2010; Williams & Deci, 1996) and internal consistency was excellent in the current study (Cronbach’s α=.93).

Perceptions of competence and doubt were measured using the competence subscale of the Basic Psychological Needs at Work Scale (Deci & Ryan, 2000), which was modified to reflect a classroom situation (Levesque-Bristol et al., 2010). The subscale contains three positively worded items and three negatively worded items. Participants responded to the six questions on a seven-point, Likert-type scale ranging from strongly disagree (1) to strongly agree (7). Example items included: “When I was in this course I often did not feel very capable,” and “I was capable of learning the materials in this course.” In the current study, an exploratory factor analysis using maximum likelihood extraction and a varimax rotation (orthogonal) indicated that the six items were better represented as two subscales, each of which contained three items. The first subscale included the positively worded items related to Competence. The second subscale included the negatively worded items and was taken to reflect Doubt in one’s abilities to meet the demands of the course environment. Validity and internal consistency for the Basic Psychological Needs at Work Scale has been documented through prior research (Deci & Ryan, 2000; Levesque-Bristol et al., 2010), and was adequate for both competence and doubt in the current study (Cronbach’s α=.82 and .77, respectively).
Data Analysis

Data were first screened as recommended by Tabachnick and Fidell (2007) and it was determined that the data met the basic requirements for inferential statistics (scores on the dependent variable approximate an interval level of measurement, scores on the dependent variable are normally distributed, observations are independent, homogeneity of variance).

Prior to conducting analyses to answer the research questions, the researchers performed two separate manipulation checks. The first examined differences in demographic and performance variables between the students who enrolled in the course in the fall of 2012 and fall of 2013. The second examined differences in demographic and performance variables for student survey responders and non-responders in each semester separately. Pearson $\chi^2$ tests were used to determine if student groups differed in terms of gender (male or female), class rank (freshman, sophomore, junior, or senior), ethnicity (white or other), and nationality (international or domestic student). Independent samples $t$-tests were used to examine if students differed in terms of SAT composite (math + verbal) and writing scores. SAT data were used because most students were first-semester college freshmen, and college-level measures of performance (e.g., overall GPA) were not available.

The first research question was: Does formative peer evaluation improve student learning, as measured by final project grade and course grade, over summative only peer feedback? For question one, three analyses were conducted. Course grades were compared between semesters as well as between two of the main components of the cooperative learning-based final project. Analysis of Covariance (ANCOVA) procedures were used to examine differences in student performance on Final Project Planning Component, Final Project Technical Document
Component, and Course Grade between fall of 2012 and fall of 2013 while controlling for SAT composite and SAT writing scores.

The second research question was: Does formative peer evaluation improve students’ perceptions of the learning climate, increase competence, and reduce doubt over summative only peer feedback? To address question two, composite scores were created by averaging the items related to each of the three constructs (Learning Climate, Competence, and Doubt) included in the study. Analysis of Covariance (ANCOVA) procedures were used to examine differences in student perceptions of the Learning Climate, Competence, and Doubt, in the fall of 2012 and fall of 2013 while controlling for SAT composite and SAT writing scores.

For all of the ANCOVA procedures, $\eta^2$ is presented as a measure of effect size. A $\eta^2$ value between .01 and .06 is associated with a small effect, between .06 and .14 with a medium effect, and above .14 with a large effect (Warner, 2012). When using independent samples t-tests, Cohen’s $d$ is presented as a measure of effect size. A Cohen’s $d$ value between .15 and .40 is associated with a small effect, between .40 and .75 with a medium effect, and above .75 with a large effect (Cohen, 1992).

Results

Pre-analysis manipulation checks: Comparison of demographic and performance variables

Prior to conducting analyses to answer the research questions, two pre-analysis manipulation checks were performed to examine differences related to student demographic and prior-performance data. The first check sought to examine if there were differences between students enrolled in the class in fall 2012 and fall 2013. Pearson $\chi^2$ tests were used for the categorical variables of gender, class rank, ethnicity, and nationality. Table 1 summarizes the results of the
Pearson $\chi^2$ tests. There was a higher percentage of females in the fall of 2013, and there was a lower percentage of freshmen and higher percentage of seniors in the fall of 2013. There were no differences in the distribution of ethnicity or international student status between the two semesters.

Independent samples $t$-tests were used to examine differences in SAT composite and writing scores of students in the fall of 2012 and fall of 2013. Results of the analyses are reported in Table 2. For SAT composite scores, $t$-test was significant, $t(299) = 2.05$, $p = .041$, $d = .24$, which indicates that students in fall of 2012 had a higher average SAT composite score than their peers in fall 2013 (the Levene’s test was not significant so the equal variances assumed $t$-test was used).

The second manipulation check identified whether there were differences between students who elected to respond to the class perceptions survey and those who did not in each semester.

Pearson $\chi^2$ tests were used for the categorical variables of gender, class rank, ethnicity, and nationality in fall of 2012 and fall of 2013 separately. Tables 3 and 4 summarize the results of the Pearson $\chi^2$ tests. There were no demographic differences between responders and non-responders in fall of 2012. In fall of 2013, the only demographic difference was that a lower percentage of students who completed the survey were classified as other ethnicity compared to those who did not complete it.

Independent samples $t$-tests were used to examine differences in SAT composite and writing scores of survey respondents and non-respondents in fall of 2012 and fall of 2013 separately. Results of the analyses are reported in Tables 5 and 6 and indicate that in fall of 2012 completers and non-completers were not significantly different in terms of SAT composite and SAT writing scores. In fall of 2013 SAT writing scores were not significantly different for completers and non-completers, but non-completers had significantly higher SAT composite scores, $t(119) = 2.01, p = .047, d = .37$ (the Levene’s test was not significant so the equal variances assumed $t$-test was used).

Research Question 1: Relationship between formative peer feedback and student performance

ANCOVA procedures were used to examine differences in student performance as measured by Final Project Planning Component, Final Project Technical Document Component, and Course Grade in fall of 2012 and fall of 2013 while controlling for SAT composite and SAT writing scores (See Table 7). There was a significant difference between fall 2012 and fall 2013 for Final Project Planning Component after controlling for SAT composite and SAT writing scores, $F(1,297) = 15.76, p < .001, \eta^2 = .050$. This significant difference indicates that students in fall 2013 ($M = .95, SD = .11$) earned higher scores on the Final Project Technical Document Component than those in fall 2012 ($M = .88, SD = .15$). Neither of the covariates were significant.

Note: *\(p < .05\), **\(p < .01\)

There was also a significant difference between semesters for Final Project Technical Document Component after controlling for SAT composite and SAT writing scores, \(F(1,297) = 7.16, p = .008, \eta^2 = .024\). This significant difference indicates that students in fall 2013 (\(M = .94, SD = .11\)) earned higher scores on the Final Project Planning Component than those in fall 2012 (\(M = .89, SD = .15\)). Neither of the covariates were significant.

Related to Course grade, there was a significant difference between fall 2012 and fall of 2013, \(F(1,297) = 6.17, p = .014, \eta^2 = .020\). This significant difference indicates that students in fall 2013 (\(M = .90, SD = .11\)) earned higher course grades than those in fall 2012 (\(M = .86, SD = .15\)).
.12). SAT comp was a significant covariate in the model, $F(1,297) = 4.90, p = .028, \eta^2 = .016$, but SAT writing was not.

Figure 2 summarizes the results of analyses related to research question one. Final Project Planning Component, Final Project Technical Document Component, and Course Grade variables were all significantly higher in fall 2013 than in fall 2012 after controlling for SAT composite and SAT writing scores.

**Research Question 2: Relationship between formative peer feedback and classroom perceptions**

ANCOVA procedures were used to examine differences in student perceptions of the classroom experience while controlling for SAT composite and SAT writing scores (See Table 8). Specifically, students’ perceptions of the Learning Climate, Competence, and Doubt were
compared between the fall of 2012 and the fall of 2013. Related to the Learning Climate, there
was a significant difference between semesters when controlling for SAT composite and SAT
writing scores, $F(1,76) = 11.98, p < .001, \eta^2 = .136$. This significant difference indicates that
students in the fall of 2013 ($M = 5.82, SD = .90$) perceived a more student-centered learning
environment than those in the fall of 2012 ($M = 4.85, SD = 1.49$). Neither of the covariates were
significant.

Note: *$p < .01$

The difference between fall 2012 and fall 2013 was also significant for Competence when
controlling for SAT composite and SAT writing scores, $F(1,76) = 7.52, p = .008, \eta^2 = .090$. This
significance indicates that students in the fall of 2013 ($M = 5.05$, $SD = .125$) perceived a higher level of Competence than those in the fall of 2012 ($M = 4.05$, $SD = 1.72$). Neither of the covariates were significant.

ANCOVA results indicated that there was not a significant difference between students’ perceptions of Doubt in fall 2012 and fall 2013 after controlling for SAT composite and SAT writing scores. Neither of the covariates were significant.

Figure 3 summarizes the results related to research question two. Students in the fall of 2013 perceived a more student-centered learning environment and more competence than did students in the fall of 2012 after controlling for SAT composite and SAT writing scores. Differences in doubt between the semesters were not significant.

![Figure 3. Differences in Learning Climate, Competence, and Doubt between Fall 2012 and Fall 2013. **p<.01](image)

Discussion

Team work is an essential skill in negotiating life in the 21st century at work and in social settings. As students practice working in groups, they develop the ability to negotiate, share responsibilities, and communicate and can tackle a broader range of challenges. When formative peer evaluation was implemented, students earned higher grades on the final project and in the course and perceived a more student-centered learning environment with an increased feeling of competence. We do need to acknowledge that instructor growth may have some impact on interpreting the findings of this work. It is possible that instructor growth may account for some improvements in student experience documented here.

Improvements in learning climate (more student centered) and competence, and reductions in doubt have been attributed to increased student persistence (Freeman et al., 2014). If more students persist as a result of the improved experience in the fall of 2013, two outcomes may be worth considering. First, as Freemen et al. (2014) suggested, struggling students are more likely to drop courses than high-achieving students. In our study, fewer low achieving students may have dropped out during in the treatment group as a result of the improved learning climate, higher competence, and reduced doubt. This may have depressed final project and course grade scores during the fall of 2013, causing the increase documented here to be artificially low and underrepresenting the benefits shown in this study. Second, a longitudinal study may help to uncover impacts in long term college persistence as it is related to developing a sense of connectedness through improved team based projects. Peer evaluation used as a formative tool may have the potential to sustain longer term impacts as students engage more successfully with their peers, build competence, and reduce doubt.
Teamwork can be frustrating for high achieving students when other members of their team will receive equal credit without contributing at the same level. Peer team member evaluation holds students accountable, which improves the experiences of the students who want grades to be representative of effort and contribution. Peer evaluation also serves to motivate students who otherwise might not participate. Educators may consider using peer evaluation as both a feedback and accountability mechanism for students.

These results suggest that our field should consider including both formative and summative peer evaluation in educational experiences to foster student skill in teamwork as well as improve success of learning experiences. Instructors interested in implementation strategies may find Mentzer’s publication in the *Technology and Engineering Teacher Journal* to be helpful (2014).

Peer evaluation is meant to provide meaningful feedback to learners in a confirmatory, suggestive, or corrective manner (Topping, 2009). Topping (2009) argued that the amount of feedback supplied to an individual is greater than if assessed by a singular source suggesting that feedback from multiple peers and the instructor is move valuable and potentially more accurate than feedback from the instructor only. When a group of students is working closely on a task, the feedback is more individualized when assessing each other (Brutus & Donia, 2010; Topping, 2009). Additionally, when group members recognize that they will be held accountable for the quality of their work by their peers, more attention to detail and understanding of the task is discussed among the group (Cestone et al., 2008). In a study by Reese-Durham (2005), it was reported that the quality of the learning output improved with formative peer evaluation as compared to previous classes. Teamwork skills such as communication and acceptance of criticism can also be developed through peer assessment by educating students on how to honestly and professionally rate team participation (Topping, 1998). In addition, results of peer
evaluation can serve as documentation of student growth over time as evidence of student effectiveness in team environments which is increasingly critical for meeting graduation requirements and programmatic accreditation (Loughry, Ohland, & Woehr, 2014).

While assessing individual performance in groups can be beneficial, it is prudent to cover the practical issues that can arise and suggestions for mitigating them. The preparedness of the students, with respect to working in teams and evaluating peers, is critical to the success of the assessment process (Kennedy, 2005; Vickerman, 2009). In an attempt at peer assessment in a computing course, Kennedy (2005) implied that the failure of the assessment and negative perception of the process was due to the lack of understanding about team work and how to effectively rate peers. Students were reluctant to judge peers, causing tension among the groups. Kaufman, et al. (2000) provided a list of concerns with peer evaluations such as collusion among team members, inflating self-ratings, and evaluating on personal prejudices. Kaufman, et al. (2000) suggested that these concerns can be managed with a primer for students on how to complete peer evaluations objectively and the skills needed for effective teamwork. Vickerman (2009) and Chen & Lou (2004) also suggested that issues with peer evaluations can be mitigated with clear instructions on how the peer evaluations will be used in the course, as well as a validated assessment tool. King & Behnke (2005) voiced concerns with grading by incorporating peer rating data. They argued that by allowing peers to assess individual contribution to a group assignment, the instructor relinquishes full control of the grade to the team, and thus may have an issue with defending a grade if challenged. It was concluded by King & Behnke (2005) that the instructor should just assign one grade to the entire group to avoid this issue. Counter to this concern, Chen & Lou (1999) suggested that since group members spend a considerable amount
of time with one another on group assignments, they are in a good position to assess the effort of
their peers as well the individual contributions made by each member of the team.

Formative peer assessment provides feedback and students can alter their performance before the
evaluative assessment is administered. Brooks and Ammons (2003) implemented assessments
multiple times in a course, but the peer evaluations were utilized as summative assessments at the
end of each short-term team project in the course. Whether the peer evaluations are formative,
summative, or a combination of both, when a grade is assigned based on the outcome of the
evaluation, the implementation process is similar (Cestone et al., 2008). Cestone, et al. (2008)
suggested that student expectations be communicated early in the course, along with how grades
will be impacted. It is also recommended that learners are prepared for how to participate in peer
evaluations, as well as how to interpret feedback. When determining the method in which a peer
evaluation instrument will be used, the validity of the chosen evaluation instrument and the
behaviors that are to be measured are important factors to consider, especially when the results
will be factored into student grades (Baker, 2008).

Limitations

This study had a few limitations that may be considered regarding generalization to other
educational environments. Evaluation of the final project included three main components which
were a planning document, a technical document, and a multimedia presentation in video form.
The rubric for the video assessment in the fall of 2012 had a typo which artificially inflated that
component of the final project for only that semester. Thus, the comparison between semesters
represents only two of three components of the final project rather than the entire project.
Further, the grade inflation on the video assessment in 2012 would have not created more than a
1% inflation for some students in fall of 2012. The results of this work show that the fall of 2013 course grades were significantly higher, but this may slightly underrepresent the overall impact of the treatment.

Another limitation of this study was that measures of student learning were limited to course assignments, which were not subjected to rigorous validity and reliability measures. However, the assignments and rubrics used were intentionally co-developed by a team of four faculty and two instructional developers to align with the objectives of the course. The instructor of the course initiated the study collaboratively with instructors from other sections of the course and the university’s center for learning and teaching support team. The external members of the research team served to minimize the potential for instructor bias as the course sections studied were not theirs. While instructor-led studies of courses potentially introduces bias, the study was conceptualized after the conclusion of the semesters where data were collected, minimizing the impact of evaluation bias on student submissions. An additional limitation related to the instructor is that while he was an experienced faculty member, this study was set in the second and third year the course was offered at the university. This was also the first and second year this faculty member was the instructor of this course. Therefore, instructor growth during his first and second year instructing this particular course may account for some impacts on student experience.

Measures of team member contribution were self-reported by students. Students completed the rater calibration function in CATME to help support their calibration with the instrument. While these reliability and validity safeguards were in place, actual contribution was not measured – self reported and peer reported contribution was measured which can be problematic and biased as suggested by Haidt (2013) and Barbara (2002). On the other hand, Fehr and Gächter (2000)
and Henrich and Boyd (2001) suggested that students are very willing to punish non-cooperating students (in this case punishment comes in the form of a poor peer evaluation). Further, Henrich and Boyd (2001) suggested there may be a tendency for cooperation to potentially stabilize as students tend to copy the most successful students’ behaviors.

Finally, conclusions drawn from the Learning Climate, Competence and Doubt were based on data from voluntarily participating students. During the fall of 2013, significant differences existed between students who choose to respond and those who did not. Differences discovered included SAT composite scores and ethnicity. These differences should be considered when generalizing the findings in that students’ responses were biased toward students who had lower composite SAT and students who identified as white as compared to other ethnicities.

Further Research

Future research could provide additional support for this study’s hypothesis by employing a randomized control treatment in an experimental design. Research validated instruments could be used to measure student learning instead of instructor generated assignments and assessment rubrics. This study purposefully relied on student perceptions of Learning Climate, Competence, and Doubt which are related to student persistence rather than direct measures of actual Competence, for example. Additional research may holistically consider relatedness and student autonomy which were aspects of Self-Determination Theory not directly measured in this study. Further, trends in student contribution and their potential changes across time in a repeated measures design may shed light on how students develop teamwork skills and what “dosage” of peer feedback is appropriate for causing changes. Other measurable indicators of team success might illustrate a larger perspective including overall satisfaction with the course, ability to
collaborate with students from other cultures, communication skills, ability to reflect, and ability to respond positively to criticism.
Appendix A: Questions included on the student perceptions survey Learning Climate, Competence and Doubt Scale Items

All items measured on a 7 point Likert type scale ranging from strongly agree to strongly disagree.

**Learning Climate Questionnaire**
1. My instructor provided me with choices and options on how to complete the work.
2. My instructor understood my perspective.
3. My instructor encouraged me to ask questions.
4. My instructor listened to how I would like to do things.
5. My instructor tried to understand how I saw things before suggesting a new way to do things.
6. My instructor stimulated my interest in the subject.
7. My instructor made sure I really understood the goals of the course and what I needed to do.

**Competence and Doubt**
1. Competence
   a. People in this course told me I was good at what I was doing.
   b. I was able to learn interesting new skills in this course.
   c. Most days I felt a sense of accomplishment from being in this course.
2. Doubt
   a. I did not feel very competent in this course.
   b. In this course I did not get much of a chance to show how capable I was.
   c. When I was in this course I often did not feel very capable.
