ABSTRACT
Diverging Diamond Interchanges (DDIs) are an emerging interchange configuration that eliminates the need for left-turn phases in conventional diamonds and may be less expensive to construct than some alternative geometries. This paper examines signal timing for DDIs. To date, DDI signal timing has typically used two-phase configuration reflecting the two competing movements at the crossover points at each intersection of the DDI. This configuration inherently contains some inefficiency: i) there is potential for internal queues under two-phase configuration, and ii) it is possible for the inflow demand to exceed outflow capacity of the interchange.

This paper uses high-resolution event data to develop performance measures to evaluate operations at a DDI in Salt Lake City, Utah. Alternatives to the existing signal timing within the two-phase configuration are modeled and tested with a field deployment. The field deployment demonstrated the ability to prioritize ramp or thru vehicles within the two-phase configuration. Additionally, a new three-phase configuration was developed and deployed to address the internal queues that occur under two-phase timing. Under this new configuration, the flows from one DDI intersection to the other are balanced and progression within the DDI is improved. By implementing the three-phase configuration, the percent of vehicles arriving on green at the heaviest internal movement within the DDI increased from 53% to 92%. To qualitatively illustrate these performance measures and improved DDI operation, a video from a tethered unmanned aerial vehicle (UAV) was prepared that demonstrates the vehicle arrival characteristics by overlaying vehicle detection and signal state graphics on the video.
High-Resolution Controller Data Performance Measures for Optimizing DIVERGING DIAMOND INTERCHANGES AND OUTCOME ASSESSMENT WITH DRONE VIDEO

OFFSET ADJUSTMENT PERFORMANCE

THREE PHASE OPERATIONS & SPLIT BALANCE

EMPIRICAL OUTCOME

MOVEMENT REPRIORITIZATION

CONCLUSIONS

DDIs are relatively rare and as agencies bring them on line it is important to have automated performance measures for characterizing their performance as well as identifying opportunities for agencies to improve timings. This paper has extended PCD and flow profile techniques to characterize DDI performance and identify operational improvements using high resolution controller data from the DDI at SR-201 and Bangterer Highway in Salt Lake City, Utah. Three-phase operation is most appropriate to consider with heavy thru movement volumes, especially when both the ramp and external thru movements are heavy. External queuing outside of the DDI and throughput through the DDI were not quantitatively measured.
