(Received 14 December 2012; published 30 April 2013)

We combine the finite-size scaling method with the mesh-free spectral method to calculate quantum critical parameters for a given Hamiltonian. The basic idea is to expand the exact wave function in a finite exponential basis set and extrapolate the information about system criticality from a finite basis to the infinite basis set limit. This is done by expanding the exact wave function in a complete basis set and use the number of basis functions to play the role of system size [8]. Early work using FSS to calculate quantum critical parameters was based on expanding the wave function in Slater-type and Gaussian-type functions [9–11]. Recently, the method was also combined with the finite element method (FEM) [12,13] and B-splines expansion to achieve similar results [14].

Here we combine FSS method with the mesh-free spectral method (SM) to calculate quantum critical parameters. Recently, the mesh-free SMs have started to gain growing attention in both applications [15–19]. In these methods, the unknown functions are approximated by expansion using preselected basis sets. One of the main challenges in SM is to handle domains extended to infinity [20–26]. Many techniques were introduced to overcome this challenge, such as using exponentially decaying functions as basis sets, the truncation of the computational windows, and applying size scaling. Recently a nonorthogonal predefined exponential basis set for eigenvalue problems involving half bounded domains was introduced and used [27,28]. The set is easy to use and allows generally finding a wide range of eigenvalues simultaneously.

In this paper, the exponential basis sets are implemented in FSS analysis to obtain the quantum critical parameters for a given Hamiltonian. The presented technique is real-space mesh-free. Such real-space techniques are gaining more attention in ab initio and density functional calculations [12,29]. As a benchmark system we choose the Hulthen potential. For such a Hamiltonian, the analytical solution is known and FSS was implemented using other basis functions, hence our numerical results can be compared and analyzed. The comparison confirms the validity and efficiency of the new approach and its applicability for FSS analysis, which will be used on more complex systems.

I. INTRODUCTION

The study of how the energy levels of a given system change as one varies a parameter in the corresponding Hamiltonian is of general interest, particularly near the binding threshold, level crossings, and quantum phase transitions. In phase transitions, critical points are associated with singularities of the free energy which occur only in the thermodynamic limit [1,2]. Finite size scaling (FSS) was developed by Fisher and others [3–7] to calculate such parameters by extrapolating information from a finite system to the thermodynamic limit. In analogy, FSS was also developed to extrapolate information from a finite basis set to the infinite basis set limit in order to calculate quantum critical parameters for a given Hamiltonian. This is done by expanding the exact wave function in a complete basis set and use the number of basis functions to play the role of system size [8]. Early work using FSS to calculate quantum critical parameters was based on expanding the wave function in Slater-type and Gaussian-type functions [9–11]. Recently, the method was also combined with the finite element method (FEM) [12,13] and B-splines expansion to achieve similar results [14].

II. THEORETICAL BACKGROUND

A. Analytical solution for the Hamiltonian with Hulthen potential

A Hulthen potential [30,31] is a special case of a Eckart potential [32], which is a family of screened Coulomb potentials. It has the following form:

$$V(r) = -\frac{\lambda}{a^2} \frac{e^{-r/a}}{1 - e^{-r/a}},$$  \hspace{1cm} (1)

where $\lambda$ is the coupling constant and $a$ is the scaling parameter. For small $r$, it resembles a Coulomb potential. But it dies faster and exponentially for large $r$.

By defining a dimensionless variable, $x = \frac{r}{a}$, and inserting the potential in a Schrödinger radial differential equation, the radial equation becomes

$$\left[ -\frac{1}{2} \frac{d^2}{dx^2} - \frac{\lambda}{1 - e^{-x}} \right] \psi = a^2 E \psi.$$ \hspace{1cm} (2)

The analytical solution for this equation is known in terms of a hypergeometric function:

$$\psi = N_0 e^{-\pi x/2} (1 - e^{-x}) \, _2F_1(2\alpha + 1 + n, 1 - n, 2\alpha + 1; e^{-x}),$$ \hspace{1cm} (3)

where $\alpha = \frac{\lambda a}{2}$, $N_0$ is a normalization constant, $\alpha$ is a parameter, and $F_1$ is a hypergeometric function.
where $\overline{\sigma} = -a^2 E$, $n$ is the state order, and $N_0$ is the normalization factor:

$$N_0 = \sqrt{\frac{(2\alpha + n)(2\alpha + n)}{\Gamma(2\alpha + n) \Gamma(2\alpha + 1) \Gamma(n)}}. \quad (4)$$

The energy levels are

$$E_n = -\frac{1}{a^2} \left( 2\alpha - n^2 \right)^2 / 8n^2, \quad \text{for } n = 1, 2, 3, \ldots, n_{\text{max}}, \quad (5)$$

It is clear from Eq. (5) that $\lambda_c = n^2/2$ is a critical coupling constant. As $\lambda_c$ is a function of $n$, it is obvious that the number of allowed bounded states (i.e., $n_{\text{max}}$) is $\lambda$ dependent. It has at least one state for $\lambda > 1/2$, and this is the critical point to be tracked.

### B. Finite-size scaling

As aforementioned, FSS method is a systematic approach allowing extrapolating the critical behavior of an infinite system by analyzing a finite sample of it. It is efficient and accurate for the calculation of critical parameters of the Schrödinger equation. Assuming that the Hamiltonian of the system is of the following form:

$$H = H_0 + V_\lambda (\lambda), \quad (6)$$

where again $\lambda$ is the coupling constant, the critical point, $\lambda_c$, will be defined as a point for which a bound state becomes absorbed or degenerate with a continuum.

As is known, the asymptotic behaviors of physical quantities near the critical points are associated with critical exponents. So the energy near $\lambda_c$ can be defined as

$$E_\lambda - E_{\lambda c} = (\lambda - \lambda_c)^\alpha, \quad (7)$$

where we assume that the threshold energy, $E_{\lambda c}$, does not depend on $\lambda$. In principle, $\lambda_c$ can be calculated, providing the exact solution. However, when use variational calculations to expand the exact wave function of the system in a basis set, only a finite number of basis functions ($N$) can be used practically. So the calculated physical observable (i.e., $E_\lambda$ in this case) depends on $N$. Thus, for each $N$, the calculated energy level is denoted by $E^{(N)}_\lambda$. FSS assumes the existence of a scaling function $F_E$ such that

$$E^{(N)}_\lambda = E_\lambda F_E (N | \lambda - \lambda_c |^\nu), \quad (8)$$

where $\nu$ is the scaling exponent for the correlation length. To obtain the numerical values of the critical parameters ($\nu, \alpha$) for the energy, we define for any given operator $\mathcal{O}$ the function

$$\Delta_{\mathcal{O}}(\lambda; N, N') = \frac{\ln(|\mathcal{O}^{(N)}_\lambda | / |\mathcal{O}^{(N')}_{\lambda} |)}{\ln(N/N')}, \quad (9)$$

If we take the operator $\mathcal{O}$ to be $H - E_{\lambda c} + \partial H / \partial \lambda$, we can obtain the critical parameters from the following function [8]:

$$\Gamma_{\alpha}(\lambda, N, N') = \frac{\Delta_{\mathcal{O}}(\lambda; N, N')}{\Delta_{\mathcal{O}}(\lambda_c; N, N') - \Delta_{\mathcal{O}}(\lambda; N, N')}, \quad (10)$$

which at the critical point is independent of $N$ and $N'$ and takes the value $\alpha$. Namely, for $\lambda = \lambda_c$, and any values of $N$ and $N'$ we have

$$\Gamma_{\alpha}(\lambda_c, N, N') = \alpha. \quad (11)$$

Because our results are asymptotic for large values of $N$, we obtain a sequence of pseudocritical parameters $(\lambda_N, \alpha_N)$ that converge to $(\lambda_c, \alpha)$ for $N \to \infty$.

### C. Spectral methods and the exponential basis sets

Mesh-free SM is a special family of the weighted residual methods [15–18]. In these methods, the unknown functions are approximated by either an expansion or interpolation, known as a collocation method using preselected basis sets. For homogeneous and smooth computational windows, SMs work very well. But they suffer from the Gibbs phenomenon if any of the structural functions of the studied problem is not analytical. To avoid this problem, the computational window is divided into homogeneous domains where the discontinuities lie at the boundaries. This approach is known as the multidomain spectral method (MDSM) [15–19]. In general MDSM methods allow handling very complicated and discontinuous functions. This capability is very flexible as any expansion basis set can be used. In this paper the studied problem has a smooth structural function (i.e., Hulthen potential). So MDSM is not used.

In many physical problems, the extensions toward infinities decay exponentially as

$$f(x) \propto e^{\pm \beta x}, \quad (12)$$

where $\pm$ is used to cover both $\mp \infty$ with positive $\beta$. As aforementioned, this is one of the main challenges in SM [20–26]. A review paper by Shen and Wang discusses this problem in further detail [26]. Recently, a nonorthogonal predefined exponential basis set for eigenvalue problems involving half bounded domains was reintroduced [27,28]. Similar sets were introduced in the 1970s by Raffenetti, Bard, and Ruedenberg [33–35] for self-consistent field wave functions.

The set is easy to use, and it overcomes many challenges such as zero-crossing and single scaling problems by approximating the decaying domain functions by an exponential basis set which spans a wide range of decay rates as follows:

$$f(x) = \sum_{n=1}^{N} c_n u_n(x) = \sum_{n=1}^{N} c_n e^{-\beta_n x}, \quad (13)$$

where $c_n$ are the expansion coefficients and $\beta_n$ are the preselected decaying rates. They are chosen intuitively based on the studied problem. But they should allow many possible decay rates with a very small number of bases. In this paper, the decaying rates are defined as

$$\beta_n = 10^{p_n}, \quad (14)$$

$$p_n = d_s + n - 1 / N - 1 (d_c - d_s), \quad (15)$$

where $d_c$ and $d_s$ are the smallest and largest powers used, respectively, and $N$ is the number of the used bases.

In this paper, the set is modified slightly to have a faster convergence by enforcing the states to vanish at $x = 0$. The modified set is

$$f(x) = \sum_{n=1}^{N} c_n u_n(x) = \sum_{n=1}^{N} c_n e^{-\beta_n x}, \quad (16)$$

where $\beta_n$ is as defined in Eq. (14).
III. IMPLEMENTATION

A. Formulation

To simplify the moments calculations, the normalized Schrödinger radial differential equation [Eq. (2)] is rewritten as

\[
\left[-\frac{1}{2}(1-e^{-x}) \frac{d^2}{dx^2} - \lambda e^{-x}\right] \psi = a^2 E_{\lambda,a}(1-e^{-x}) \psi.
\]

The expansion form [Eq. (16)] is used to solve the above equation. For each used number of basis \( N \), the expansion form is rewritten as follows:

\[
\psi(N)(x) = \sum_{n=1}^{N} c_n^{(N)} e^{-\beta_n^{(N)} x}.
\]

This form is working only for bounded states and hence should work fine only for \( \lambda > 0.5 \). By implementing this expansion form, Eq. (17) can be written as

\[
(A_N + \lambda B_N) \psi^{(N)}_n = a^2 E_{\lambda,a} O_N \psi^{(N)}_n,
\]

where the elements of the matrices are the following scalar products:

\[
[A_N]_{mn} = [e^{-\beta_n^{(N)} x}] - \frac{1}{2x} \left[ \left(\beta_n^{(N)}\right)^2 x - 2\beta_n^{(N)} \right] - \lambda [e^{-\beta_n^{(N)} x}] \bigg|_{1D}
\]

\[
= \frac{1}{\beta_m^{(N)} + \beta_n^{(N)}} - \frac{1}{\beta_m^{(N)} + \beta_n^{(N)} + 1}
\]

\[
[B_N]_{mn} = \left[ e^{-\beta_n^{(N)} x} \right] \frac{1}{x} \left[ e^{-\beta_n^{(N)} x} \right] \bigg|_{1D}
\]

\[
= \frac{1}{\beta_m^{(N)} + \beta_n^{(N)}} - \frac{1}{\beta_m^{(N)} + \beta_n^{(N)} + 1}
\]

\[
[O_N]_{mn} = \left[ e^{-\beta_n^{(N)} x} \right] - \frac{1}{x} \left[ e^{-\beta_n^{(N)} x} \right] \bigg|_{1D}
\]

\[
= \frac{1}{\beta_m^{(N)} + \beta_n^{(N)}} - \frac{1}{\beta_m^{(N)} + \beta_n^{(N)} + 1}.
\]

In the above equations, the integrations are taking place in one dimension and not over the physical three-dimensional space. Equation (19) is a direct eigenvalue problem, and by selecting proper values for \( d_s \) and \( d_c \), a wide range of eigenvalues \( E_{\lambda,a}^{(N)} \) and their corresponding eigenstates \( c_n^{(N)} \) can be calculated directly. The used values for \( d_s \) and \( d_c \) are \(-4 \) and \( 4 \), respectively.

In this paper we focus on the critical change in the lowest energy level. So in the remainder of this paper, \( E_{\lambda,a}^{(N)} \) is corresponding to the calculated ground state level with \( N \) basis; clearly it is a function for \( \lambda \) and the scaling factor \( a \). Also, \( c_n^{(N)} \) is corresponding to the ground state, and it contains the expansion coefficients. Generally, the states need normalization by dividing the coefficients by \( N^{(N)}_{f,\lambda} \), where

\[
(N_{f,\lambda}^{(N)})^2 = 4\pi \sum_{m,n} c_m^{(N)} c_n^{(N)} \int_0^{\infty} x^2 e^{-(\beta_m^{(N)} + \beta_n^{(N)}) x} dx
\]

\[
= 4\pi \sum_{m,n} c_m^{(N)} c_n^{(N)} \frac{2}{(\beta_m^{(N)} + \beta_n^{(N)})^2}.
\]

In this case and the following calculations for the potential energy, the integrations are calculated over the physical three-dimensional space for the case of \( l = 0 \).

To apply FSS as shown later, we need to calculate the potential energy. It is simply

\[
V_\lambda^{(N)} = -4\pi \lambda \sum_{m,n} c_m^{(N)} c_n^{(N)} \int_0^{\infty} x e^{-(\beta_m^{(N)} + \beta_n^{(N)} + 1) x} dx.
\]
The integrations are computed numerically by Gaussian quadrature. Obviously this is the most numerically expensive part in work. However, it is clear also that the integrations are independent of the state-distinctive parameters (i.e., $\lambda$ and $c(N)$). So, for each $N$, the integrations are calculated at the beginning, and the results are used to calculate $V_{\lambda}^{(N)}$ while varying $\lambda$.

To obtain the critical parameters, we use the following shifted functions:

$$\Delta_F(\lambda; N, N', N'') = \frac{\ln \left( \frac{E_{\lambda}^{(N')}-E_{\lambda}^{(N)}}{E_{\lambda,a}^{(N')}-E_{\lambda,a}^{(N)}} \right)}{\ln(N'/N)}$$

(25)

and

$$\Delta_F(\lambda; N, N', N'') = \frac{\ln \left( \frac{V_{\lambda}^{(N')}-V_{\lambda}^{(N)}}{V_{\lambda,a}^{(N')}-V_{\lambda,a}^{(N)}} \right)}{\ln(N'/N)}.$$ 

(26)

The critical parameters $\lambda_c$ and $\alpha$ can be obtained from $\Gamma_\alpha$ as defined in Eq. (10).

B. Results and discussion

In the calculations, the scaling parameter ($\alpha$) is set to one. Also as aforementioned, the used parameters for the exponential basis set are $-4$ and $4$ for $d_s$ and $d_e$, respectively. These parameters are chosen after few iterations to have a reasonable accuracy for the eigenvalues. To implement FSS, $N$ is varied between 32 and 48 in steps of 2. So, $\lambda_c$ and $\alpha$ can be obtained by seeking the crossing of the FSS curves.

The calculated ground state energies ($E_0$) are shown in Fig. 1 as a function of $\lambda$ for all the used values of $N$. The errors are very small (as shown in Fig. 2), and hence the lines are overlapping. More resolution (in $\lambda$) is shown in the inset. As can be observed, the calculated values for the ground state energy start diverging slightly from the exact solutions as $\lambda$ approaches $\lambda_c$. This is expected as the used basis works for bounded states, and the error will increase as the states get extended in space. However, the calculated values of $E_0$ are still very accurate, and a relative error of about $10^{-10}$ was obtained around $\lambda = 0.51$ for $N = 32$ and $\lambda = 0.5001$ for $N = 48$ as shown in Fig. 2.

In Fig. 3 the results of FSS calculations are shown. Plotting $\Gamma_\alpha$ as a function of $\lambda$ for different values of $N$ gives a family of curves that intersect around the analytical $\lambda_c = 0.5$ and $\alpha = 2$. The exact crossing of any adjacent curves defines

The critical parameters $\lambda_c$ and $\alpha$ can be obtained from $\Gamma_\alpha$ as defined in Eq. (10).
the pseudocritical parameters $\lambda_N$ and $\alpha_N$, which are used to analyze the convergence.

To check the convergence, the pseudocritical parameters $\lambda_N$ (Fig. 4) and $\alpha_N$ (Fig. 5) are plotted as functions of $1/N$ and compared with the results obtained using Hermite interpolation polynomials FEM by Antillon et al. [13]. It is clear that the three methods converge to the analytical values. However, the used exponential basis set in this paper results in considerably faster convergence when compared with the other two methods. The results of the three methods are summarized in Table 1.

The last point to be presented is to confirm the validity of FSS assumptions using a data collapse calculation. In Fig. 6, $E_0N^{-\alpha/\nu}$ is plotted as a function of $(\lambda - \lambda_c)N^{-1/\nu}$ for all the used $N$ values. It is clear that all the curves overlap perfectly and thus validates our FSS assumptions.

IV. CONCLUSION

In atomic and molecular physics, the near-threshold binding is important in the study of ionization of atoms and molecules, molecular dissociation, and scattering collisions. Our benchmark calculations for the near-threshold behavior of the energy levels of the Hulthen potential indicate the validity of combining the FSS method with the mesh-free SMs to calculate quantum critical parameters. Fortunately, the exponential basis sets used in this study have been used previously as an exponential-type even-tempered basis for atomic orbitals [33–35]. The results indicate that even-tempered bases are very accurate in Hartree-Fock atomic calculations. Also, a systematic approach extending even-tempered atomic orbitals to optimal even-tempered Gaussian primitives have been developed and used decades ago in standard quantum chemistry calculations for atomic and molecular system [33,34,36,37]. Thus, our combined FSS method and SMs based on even-tempered basis sets might be used to extract quantum critical parameters for atomic and molecular systems. In future studies, we plan to combine our FSS procedure with the Hartree-Fock and density functional theory and other ab initio methods using SMs with even-tempered basis and other intuitive basis sets to analyze criticality and near-threshold phenomena for molecular and extended systems. The presented approach allows scaling to analyze large systems.
