This document has been made available through Purdue e-Pubs, a service of the Purdue University Libraries. Please contact epubs@purdue.edu for additional information.
Electronic commerce did not emerge with the development of the World Wide Web or the commercialization of the Internet. It has been around for over 25 years. It germinated in 1948 during the Berlin airlift when Ed Guilbert of the Department of Defense spearheaded the Transportation Data Coordinating Committee. This group needed to get various modes of transportation (air, railroad, and ocean) to share data like schedules and to coordinate with each other and with their clients to effectively deliver goods and supplies. This eventually led to the establishment of the X12 committee which was accredited by ANSI (American National Standards Institute) in 1979. Large petroleum, banking, transportation, and retailing companies and the federal government soon began using X12 EDI (Electronic Data Interchange) to provide electronic forms and messages for shipping and purchasing. However, the book industry had already begun establishing communication standards in 1974.

It is easy to equate Electronic Data Interchange with electronic commerce, but EDI is really only one element of electronic commerce. We can describe Electronic Data Interchange as the communication of business information using "a collection of standard message formats and element dictionaries to exchange data." It is a set of standards that facilitate business to business processes such as ordering and fulfillment and financial transactions. Electronic commerce, on the other hand, could be defined simply as "doing business electronically." The concept implies the exchange of information over computer networks; but it also involves online querying of supplier databases and the real-time integration of supply chains over the Internet and extranets. Electronic commerce could use structured communications (such as EDI) or unstructured messages (such as email) to transmit information, data, databases, database access, or a combination of these. Electronic commerce comprises at least three types of communications: consumer to consumer, consumer to business, and business to business and it implies electronic links between the various sources of information.

We shall begin by reviewing the origin and development of standards for Electronic Data Interchange, considering exceptions and variations that standards need to accommodate, and examining cost factors that affect implementation decisions. We shall then proceed to discuss conducting EDI over the Internet and the importance of metadata and data type definitions for interpreting data structures and improving functionality of business transactions. Then, we'll look at XML (Extensible Markup Language) as a proposal to broaden the applicability of transacting business over the Internet by bringing EDI to the desktop. We shall consider how XML could work for EDI over the Internet and the benefits that it could affect.

**Origin and Development of EDI Standards**

Although humans have long envisioned that computers would improve communication and data interchange for commercial applications, reality usually required developing custom interfaces for each different system to facilitate transactions with suppliers and customers. In the six years from its creation, in 1974, until the Book Industry Systems Advisory Committee (BISAC) became a committee of the Book Industry Study Group (BISG) in June, 1980, BISAC aimed to streamline the ordering and supply of books and printed materials. It developed formats for purchase orders, order acknowledgment, invoice, title status, payment advice, frontlist diskette, data transmission protocols, royalty statement, and sales reporting.

In 1979, the American National Standards Institute (ANSI) Accredited Standards Committee (ASC) X12 began to develop uniform standards for the electronic exchange of business transactions in standards known as electronic data interchange (EDI). Around 1983, the major BISAC members wanted BISAC to develop formats based on the X12 formats to allow the book industry to follow standards comparable to other industries and supported by standardized "translators" and value added networks.

The ASC X12 committee meets three times a year to develop and maintain EDI standards. The committee's main objective is to "develop standards to facilitate electronic interchange relating to such business transactions as order placement and processing, shipping and receiving information, invoicing, and payment and cash application data, and data to and from entities involved in general business, finance, insurance, education, and state and federal governments."

The ASC X12 standards aim to facilitate electronic commercial transactions by establishing a common, uniform business language for computers to communicate. They comprise more than 300 transaction sets that allow businesses to execute nearly every type of business-to-business operation electronically, such as orders, invoices, customs declarations, statistics, insurance documents, bills of transport, and many health care transactions. They are often the electronic equivalent of the preprinted forms sold in stationery stores. The goal was not to replace paper forms with electronic equivalents, but to allow businesses the flexibility to reengineer how work is processed in order to gain efficiencies of working electronically via EDI. Those companies that closely examined their work processes benefited more than those who just replaced paper forms with electronic forms.

The EDI standards have even become recognized internationally and have received endorsement by the United Nations which developed the UN/EDIFACT standard (United Nations Standard Messages Directory for Electronic Data Interchange for Administration, Commerce, and Transportation), in many respects, based on lessons learned in X12's development experiences. UN/EDIFACT messages use predefined field identifiers which must occur in a predefined sequence. Some users claim it is less robust than ANSI ASC X12. Others say the opposite. But its widespread acceptance makes it viable. EDI got further endorsement in 1997, when President Clinton decreed that all U.S. government procurement be accomplished via electronic commerce. The U.S. government then began moving toward adopting and implementing X12 and UN/EDIFACT.

**Exceptions and Variations**

Every industry has its own way of doing things. Not only must international standards accommodate possible variations by industry and company, they must also take into consideration each country's own set of exceptions. Even within the same industry,
many companies operate differently. It is not uncommon to add comments on a purchase order to clarify what one wants or the terms of delivery, for example. Standard EDI messages must support these comments and many other options that make them very complex. This complexity, resulting from the differences between trading partners and the related costs of programming or mapping data, discourage many companies from implementing EDI.

Also, in the development of international EDI standards, language becomes important. We take it for granted that the data elements and syntax use English. English is a dominant language in the business world and the Internet is based on English syntax and almost every program is coded in English language friendly computer languages. However, have French or Chinese vendors and buyers, for example, been willing to use English? Should the data elements be language neutral or should multiple naming conventions and syntaxes be used?

Cost Factors

EDI messages serve to exchange documents or data between companies. However, different organizations store their data in different formats and representations (data layouts). One company may store its data in a relational database, for example, and may have to map it differently for transmission via EDI. Such mapping can be very involved and costly.

In addition to the costs of programming and data mapping, companies incur high costs in acquiring and implementing EDI. These costs include hardware, setup, EDI enabling software, transaction service fees, telecommunications charges, and annual software maintenance contracts that the ongoing evolution of EDI standards require.

Companies must realize sizable savings to break even. Because the quantity of documents exchanged determines the amount of savings, large companies that process many transactions can offset their costs in a relatively short time. Small and medium-sized organizations, on the other hand, will find it harder to justify EDI. Large companies can offset the cost of EDI through increased efficiency. Smaller companies, however, can find the costs prohibitive, excluding them from revenue opportunities. For example, some large companies, particularly those in low-margin retail businesses such as WalMart and Kmart, refuse to conduct business with any company that does not use EDI.

The wide range of interfaces employed by users further complicates implementation and support. In addition to creating, or contracting with a software vendor to create, a custom interface for every trading partner with which it exchanges data, a company must deal with the complexity and expense of custom user interfaces that must be created for each new form, document, or process. This makes EDI a complicated and expensive proposition for many.

EDI Over the Internet

EDI has been most successful in vertical markets and in business-to-business transactions with a large number of interactions. The advent of the Internet and its use for business applications changed how people interact when they exchange goods and services. EDI is no longer restricted to business to business communications. The Internet has introduced many new ways of trading, allowing interaction between groups that previously could not afford to trade with one another economically. The same principles apply to all commercial transactions, whether the consumer is an end user, a manufacturer, a service organization, a governmental agency, or a virtual organization. So all participants in the electronic marketplace should be able to transact business with the same ease.

The Internet Engineering Task Force (IETF), a large open international community of network designers, operators, vendors, and researchers concerned with the evolution of the Internet architecture and the smooth operation of the Internet, is part of The Internet Society that develops Internet standards. Much of its work is done in its working groups. Some of these groups are concerned with business communications and should be making recommendations for implementing standards of commerce over the Internet.

A major challenge to performing EDI on the Internet is to reduce the cost of doing EDI enough to allow small and medium-sized organizations to realize savings also. The goal is to enable them to perform EDI transactions with only a browser and an Internet connection. The application of eXtensible Markup Language (XML) to EDI on the Internet promises to do just that.

Metatags and Data Type Definitions

By using metatags, such as those employed in XML, to identify data elements, companies can tag their data once and use it with any number of applications, such as in the preparation of catalogs, purchase orders, and invoices. The tags also allow for distinguishing different meanings for the same word. For example, one could use different tags to identify the term "pocketbook" as a purse, a billfold or wallet, or a small book. The term "date" with no qualifiers could indicate an order date, a shipping date, a received date, a social engagement or a person's companion on such an outing, or even a fruit.

continued on page 88
XML tags and attributes can incorporate long-established messaging structures and rules that vary from industry to industry into Web-based documents for Electronic Data Interchange between trading partners. This could streamline the purchase of goods and open the supply chain to any trading partner with an Internet connection and an XML-capable browser. It could also facilitate the entry of smaller companies into the electronic marketplace by allowing vendors to offer products directly to a buyer, effectively removing the middleman because all processing is done on the client side, the buyer’s computer. Buyers and suppliers of all sizes can participate in commerce over the Internet because it does not require the use of proprietary technologies.

As the ANSI ASC X12 and UN/EDIFACT standards have already devised structured messages for most types of business transactions, it’s very likely that they can serve as the basis for XML Data Type Definitions (DTD) for commercial transactions. The DTD and metadata will be most useful when used by a number of people and tools. However, in the real world, people often agree to comply with the standards, then modify them a little or a lot to suit their own needs and those with whom they are communicating. While XML offers a high degree of flexibility, industry users will need to resolve how to establish data dictionaries and how to make those dictionaries usable to general purpose electronic commerce applications. Brian Green, Secretary of the European Book Sector EDI Group, expects that EDIEUR will soon begin developing data neutral data dictionaries which will allow UN/EDIFACT tags to be used by XML or any other language that uses metadata.

Part of the problem of implementing EDI in the library market is the very complex product description. The MARC format could serve as the DTD for library applications as it contains all the information needed by librarians and anybody working in the book trade. However, any changes will likely occur over a long period of time, and business requirements will determine how this will all evolve.

A DTD could serve to specify the structure of a document and how to interpret it, much like a template. The creation of a template in this fashion could enable users to create the equivalent of EDI messages without the labor and cost of extensive data mapping. Libraries process an enormous number of transactions; but the relatively low price per item and small margins currently militate against widespread implementation of EDI. By implementing XML, however, librarians and vendors can process messages on the client side, further reducing costs and processing overhead.

Metatags Mean Greater Functionality

Today’s search engines can easily extract information from textual databases and Web pages. But some form of tagging system must be used to retrieve “fielded” data accurately. XML/EDI and the use of metatags permit using structured data along with unstructured text in the same document. These metatags allow searching, indexing, manipulating, and displaying data consistently and correctly without the need to create special interfaces. They could also enhance commerce on the Web by adding new dimensions not currently available. For example, if online booksellers use a standard set of metatags to mark titles, descriptions, and prices, buyers could quickly search all of the online bookstores for the lowest price on a book with a single command. Books and music have emerged as the leading goods and services sold on the Internet. Zona Research Inc. (Redwood City, CA) estimated that book sales over the Internet totaled $181 million for the fourth quarter of 1997, with music trailing at $47 million. ¹ It forecasts that the number of businesses planning to conduct business over the Internet will grow by 34%. International Data Corp. (Framingham, MA) estimates that the amount of commerce conducted over the Internet will increase from $2.6 billion in 1996 to $220 billion in 2001.² The market is so lucrative that Barnes & Noble is reportedly prepared to lose $7 million dollars a year to build market share online.³ Robert Kruwirch, in an ABC News broadcast on November 24, 1998, reported that Barnes & Noble’s customer base stood at 930,000 compared to Amazon’s 4,500,000. While Amazon’s new customers increased by 1,200,000 in the last few months, Barnes & Noble only added 210,000. However, this was before the purchase of half of Barnesandnoble.com by Bertelsmann.

Online catalogs are the first applications taking advantage of XML and major European wholesalers publish monthly multimedia CD-ROM stock catalogs. Most of these catalogs allow users to build order files and to transmit them in EDI formats, normally using direct dialup. But the number of consumers who purchase goods over the Internet account for only one percent of the consumer market.

Today, only sites that have been specifi-
to its as its “presentation” layer. XML would allow the data to interface with EDI, but the underlying processing would remain EDI. XML could function with traditional methods of EDI and could support all standard Internet transport mechanisms such as IP routing, HTTP, FTP, and SMTP. It uses programming tools such as Java and ActiveX to permit data sharing between programs; and it uses agent technologies to manipulate, parse, map, and search for data.

Benefits

Leading the list of benefits of using XML for e-commerce is that it allows people and companies to exchange information more clearly and completely than previous formats. It lets users conduct business transactions at the client level on desktop computers with a general purpose document or Web browser as the user interface. A common language describes the templates and associated conversion rules. Even though XML/EDI allows distributed processing capabilities, it also supports centralized functions. It lets users be more independent, permitting them to define and issue documents rather than relying on data processing specialists to do so.

Instead of having to create templates and interfaces for each trading partner, traditional EDI service providers will just need to interlace their products to XML/EDI templates. As companies implement XML/EDI to provide simpler and use types of transaction tools, businesses that fail to incorporate XML/EDI into their operations will limit their growth and may see their products eliminated from the marketplace because their competition will have made it easier to do business with them.

Because XML/EDI supports legacy or traditional EDI systems by definition, companies that use UN/EDIFACT or ASC X12 standards can continue to use their systems. They can create a conversion routine (gateway) between the subsystems that use UN/EDIFACT or ASC X12 and those that use XML/EDI to interface with clients or suppliers who are reluctant to adopt XML/EDI. Business requirements will determine how this will all evolve and will likely occur over a long period of time.

Some businesses are starting to look at XML as a means to reduce procurement costs when buying goods over the Internet. CommerceOne has a product, BuySite, that automates the procurement process from requisition to order. Its MarketSite software then automates the interaction with the supplier from order placement to payment. The company expects that integrating XML will reduce operational costs and increase efficiency because of its ability to define products so buyers can search the online catalogs to iden-

to their contributions. Stated simply, it would be built upon the shared cataloging economic model (participants contribute scanned books instead of bibliographic records), but with the revenues shared by the participants instead of being held by the bibliographic utilities. The price to use the database of collaboratively digitized books would need to be set at a level to encourage use. The profits derived (to be shared by those contributing content) would need to be at a level to encourage the contribution of content. In this sort of model, universities, libraries, and publishers can all be winners.

The strengths of this model includes putting the acrimony and hostility that has characterized our relationship behind us while at the same time increasing the amount of information that one can access without seeking each member's fiscal destruction. The weakness of this model is that collaboration seems to be an unnatural act. Libraries have seldom been able to cooperate with each other, let alone publishers. Or can we?

So what will our collection development future be like? Three potential models have been reviewed. I am sure each person who reads this could supply others. Just remember, be careful of what you wish for, you might just get it.

ify the right product at the right price.

We briefly reviewed the history of the development of standards for Electronic Data Interchange, considered some of the exceptions and variations that standards need to account for, and examined cost factors that affect decisions to implement EDI. We discussed how the Internet is changing expectations for electronic business transactions; and we considered XML as an emerging solution. By applying object-oriented technology to EDI, XML uses metatags and data type definitions to interpret data structures and improve the functionality of business transactions. XML promises to allow clients to implement EDI with a minimum of effort, thereby reducing costs. Implementation will not occur overnight. The change will be evolutionary rather than revolutionary. As applications get updated and modified with XML code, these solutions will gradually replace older, more cumbersome applications. In the meantime, several companies and organizations have begun to adapt existing standards or to prepare DTDs for use with XML. Others are developing tools to facilitate the transition.
